

Design

UI:

For the UI, please refer to the index.html. As explained in the screencast, I wasn't able to complete this fully. But, I have a partial set of code. I am facing some issues because of ajax. I will try to fix it sooner.

API gateway:

Successfully, created an API gateway with the post request with CORS enabled. As mentioned in the video, I could get the response. In the design, API gateway mediates between UI and lambda. It redirects the request to lambda to get the response

Lambda:

Created a simple lambda service (lambda_function.py) that gets a response from sagemaker and sends it back to the UI.

Sagemaker and model_script: (Aws_sagemaker.py and model_script.py)

Model_script creates a sklearn stochastic gradient descent model with some hypertuning and provides prediction and confidence. I completely restructured from a normal sagemaker script template to facilitate my model building.

After this, sagemaker model is built and deployed as an endpoint. And, that endpoint is used in lambda to get the response.

Please note that my code wouldn't contain many comments, but please consider this document as an explanation for all my code.

Model experimentation:

I experimented with different models before going for the sgdc classifier. In experimentation/document_classification.py, we could see my experimentation. Utilized precision, recall and f measure to choose the model. Sgdc performed equally well with respect to different variables.

As for the UI, I am facing an internal service error when I send a request to the lambda service. Even though, I uploaded a partial working UI to S3 bucket, due to its incompleteness, I couldn't share the S3 url.

But, I am happy to announce I got the web service working. Given a few more hours, I could get the UI working, but the deadline is over.

I request you to consider all my contributions and efforts irrespective of an incomplete UI.

Thank you.
